

Decision Trees

Emily Fox & Carlos Guestrin
Machine Learning Specialization
University of Washington

Predicting potential loan defaults

What makes a loan risky?

Credit history explained

Did I pay previous
loans on time?

Example: excellent,
good, or fair

Income

What's my income?

Example:
\$80K per year

Loan terms

How soon do I need to pay the loan?

Example: 3 years,
5 years,...

Personal information

Age, reason for the loan, marital status,...

Example: Home loan for a married couple

This module ... decision trees

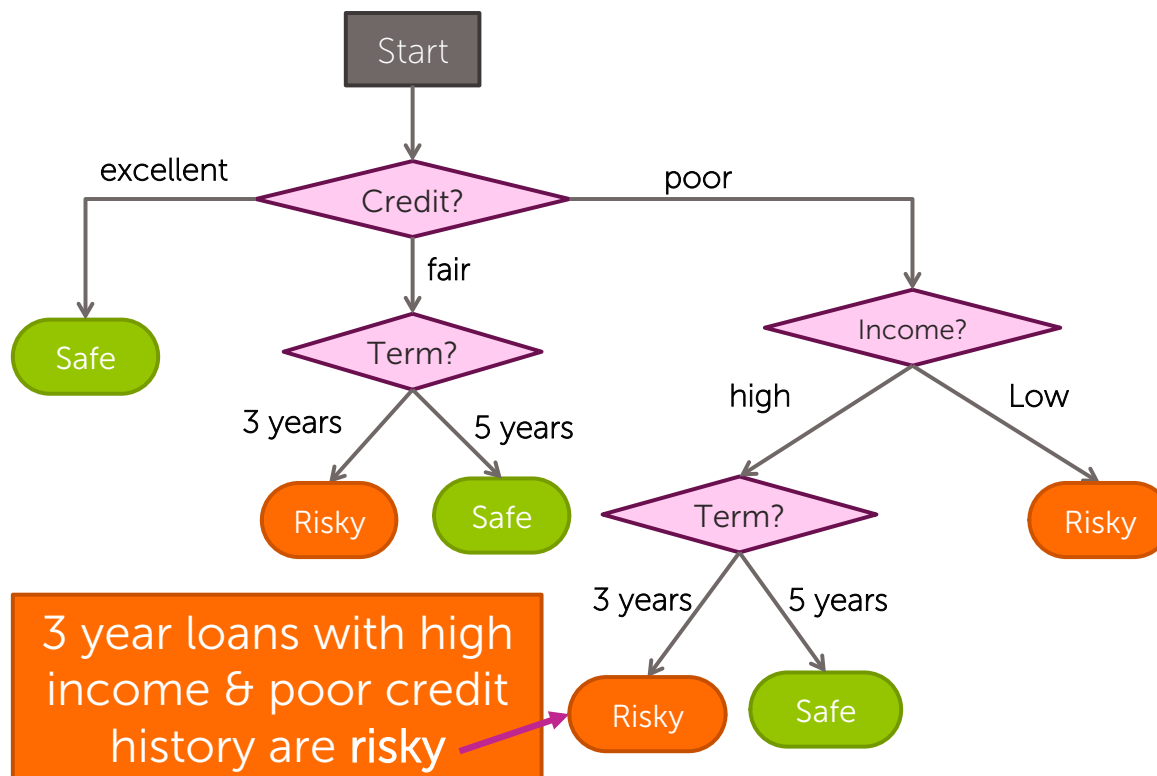

Decision trees: *Intuition*

What does a decision tree represent?

What does a decision tree represent?

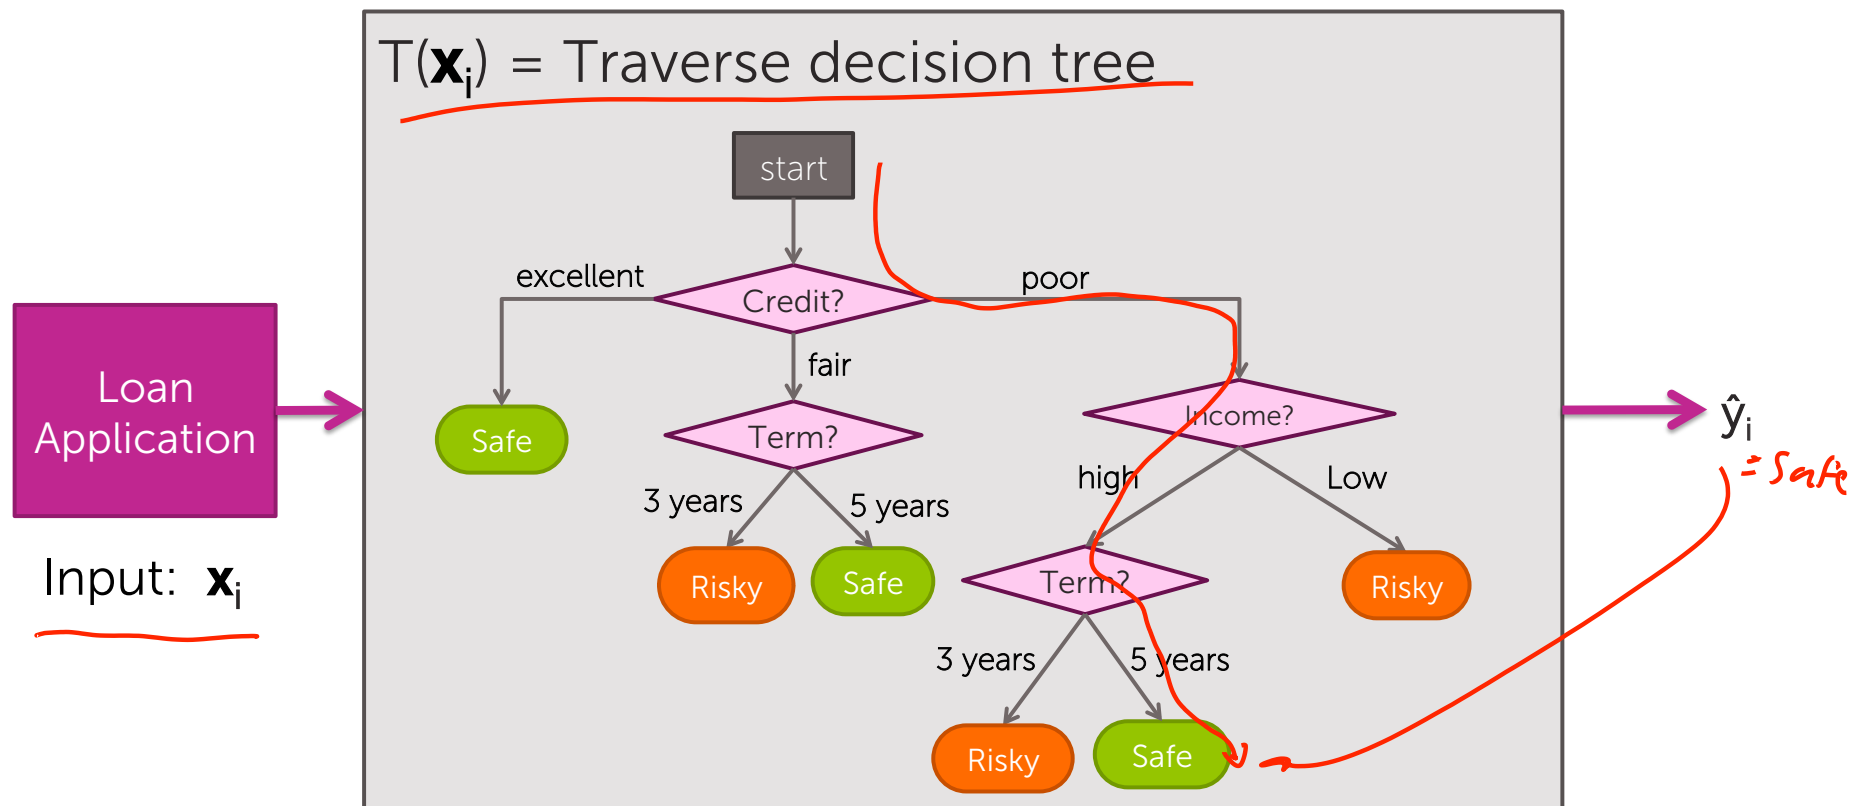

Scoring a loan application

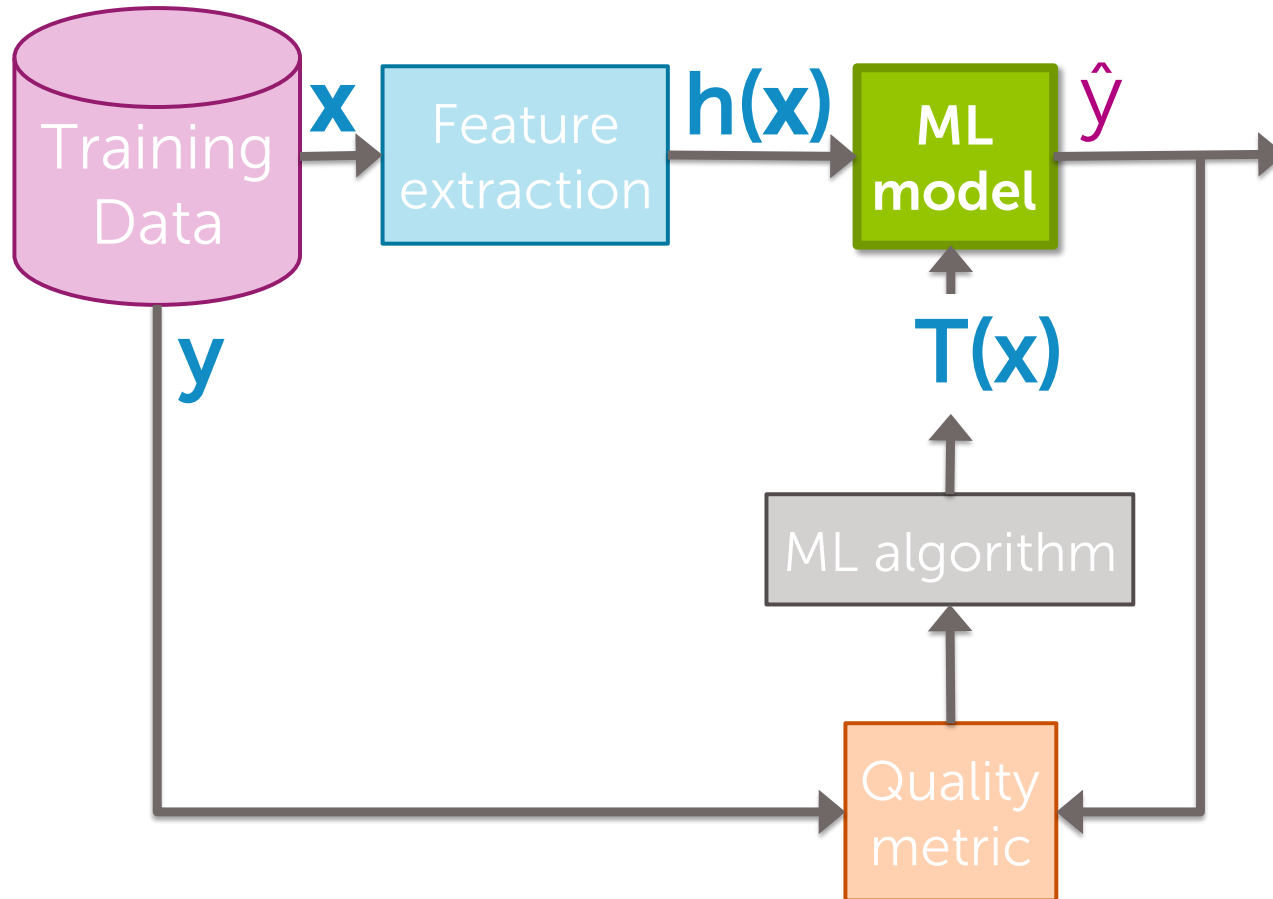

$\mathbf{x}_i = (\text{Credit} = \text{poor}, \text{Income} = \text{high}, \text{Term} = 5 \text{ years})$

Decision tree model

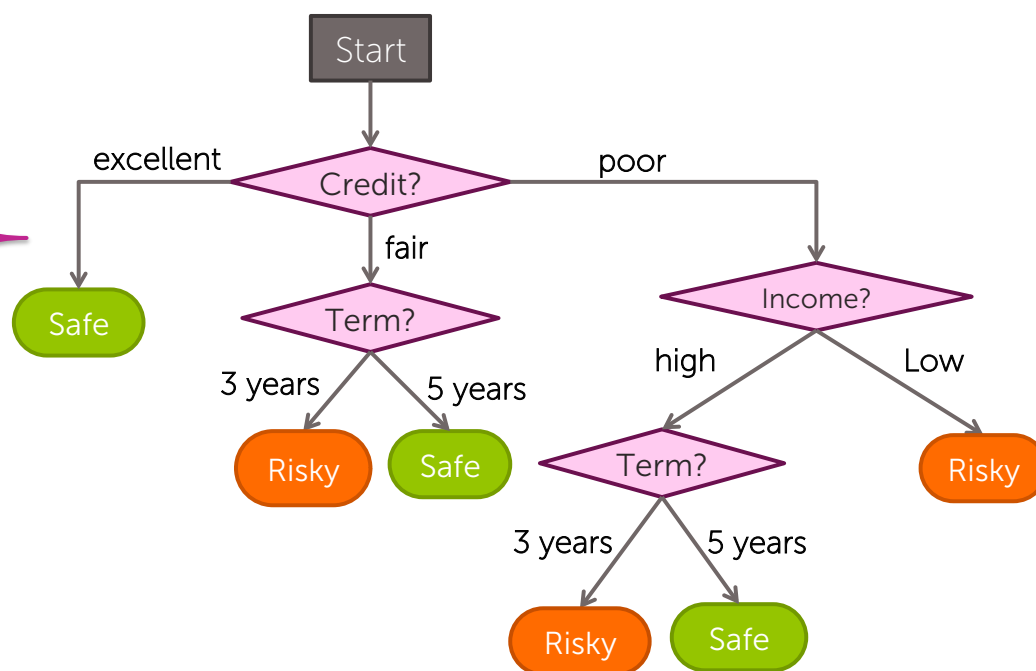

Decision tree learning task

Learn decision tree from data?

$h_1(x)$	$h_2(x)$	$h_3(x)$	Loan Status
Credit	Term	Income	y
excellent	3 yrs	high	safe
fair	5 yrs	low	risky
fair	3 yrs	high	safe
poor	5 yrs	high	risky
excellent	3 yrs	low	risky
fair	5 yrs	low	safe
poor	3 yrs	high	risky
poor	5 yrs	low	safe
fair	3 yrs	high	safe

Decision tree learning problem

Training data: N observations (\mathbf{x}_i, y_i)

Credit	Term	Income	y
excellent	3 yrs	high	safe
fair	5 yrs	low	risky
fair	3 yrs	high	safe
poor	5 yrs	high	risky
excellent	3 yrs	low	risky
fair	5 yrs	low	safe
poor	3 yrs	high	risky
poor	5 yrs	low	safe
fair	3 yrs	high	safe

Quality metric: Classification error

- Error measures fraction of mistakes

$$\text{Error} = \frac{\text{\# incorrect predictions}}{\text{\# examples}}$$

- Best possible value : 0.0
- Worst possible value: 1.0

Find the tree with lowest classification error

Credit	Term	Income	y
excellent	3 yrs	high	safe
fair	5 yrs	low	risky
fair	3 yrs	high	safe
poor	5 yrs	high	risky
excellent	3 yrs	low	risky
fair	5 yrs	low	safe
poor	3 yrs	high	risky
poor	5 yrs	low	safe
fair	3 yrs	high	safe

Minimize
classification error
on training data

$T(X)$

How do we find the best tree?

Exponentially large number of possible trees makes decision tree learning **hard**!
(NP-hard problem)

Simple (greedy) algorithm finds “good” tree

Credit	Term	Income	y
excellent	3 yrs	high	safe
fair	5 yrs	low	risky
fair	3 yrs	high	safe
poor	5 yrs	high	risky
excellent	3 yrs	low	risky
fair	5 yrs	low	safe
poor	3 yrs	high	risky
poor	5 yrs	low	safe
fair	3 yrs	high	safe

Approximately
minimize
classification error
on training data

$T(X)$

Greedy decision tree learning:

Algorithm outline

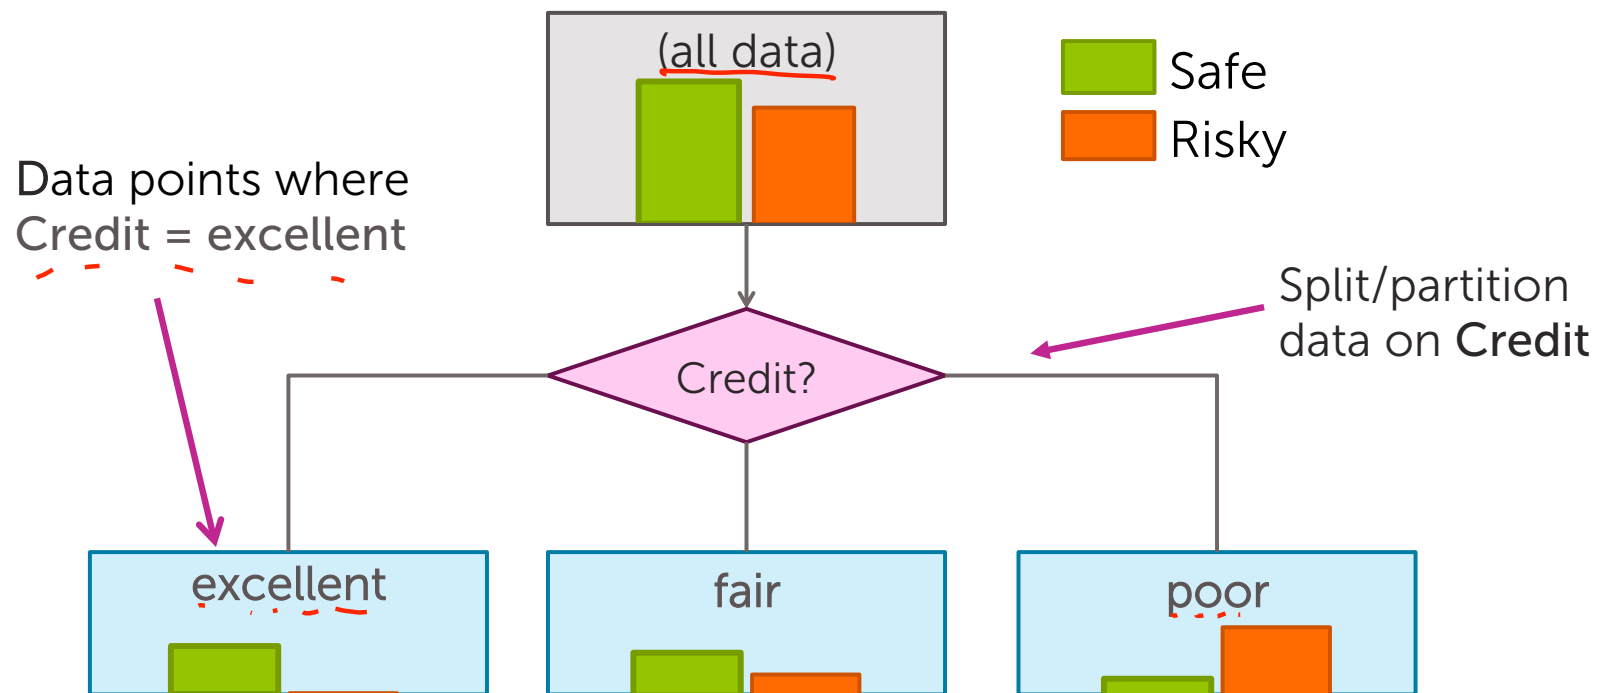

Step 1: Start with an empty tree

Step 2: Split on a feature

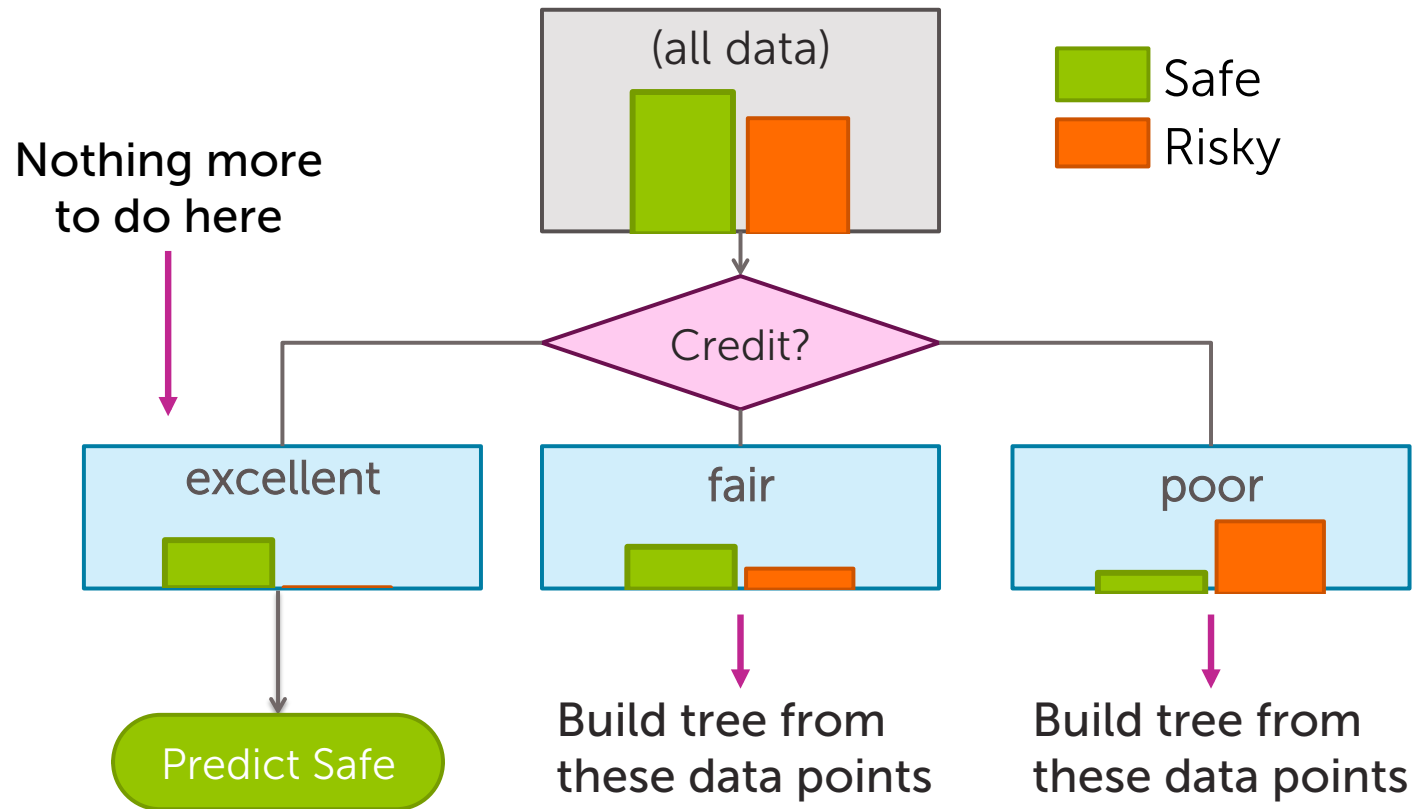

Feature split explained

Step 3: Making predictions

Step 4: Recursion

Greedy decision tree learning

- **Step 1:** Start with an empty tree

- **Step 2:** Select a feature to split data

- For each split of the tree:

- **Step 3:** If nothing more to, make predictions

- **Step 4:** Otherwise, go to **Step 2** & continue (recurse) on this split

Problem 1: Feature split selection

Problem 2: Stopping condition

Recursion

Feature split learning

=

Decision stump learning

And it turns out that this feature selection problem, this feature splitting learning problem, can be viewed as the problem of learning what's called a decision stump, which is that one level on the decision tree.

Start with the data

Assume $N = 40$, 3 features

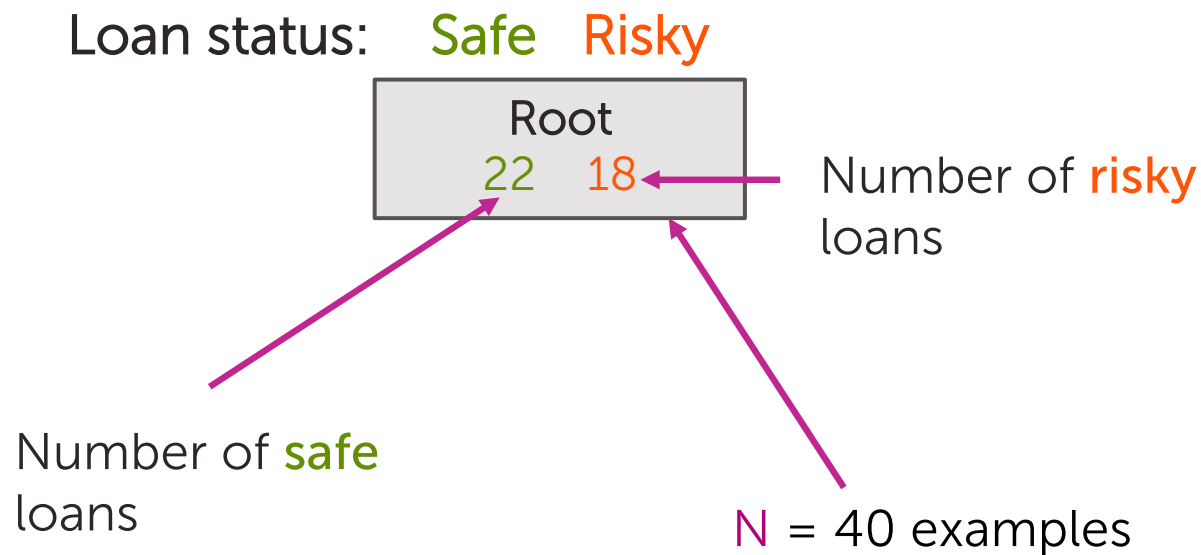

Credit	Term	Income	y
excellent	3 yrs	high	safe
fair	5 yrs	low	risky
fair	3 yrs	high	safe
poor	5 yrs	high	risky
excellent	3 yrs	low	risky
fair	5 yrs	low	safe
poor	3 yrs	high	risky
poor	5 yrs	low	safe
fair	3 yrs	high	safe

Start with all the data

Loan status: **Safe** **Risky**

Compact visual notation: Root node

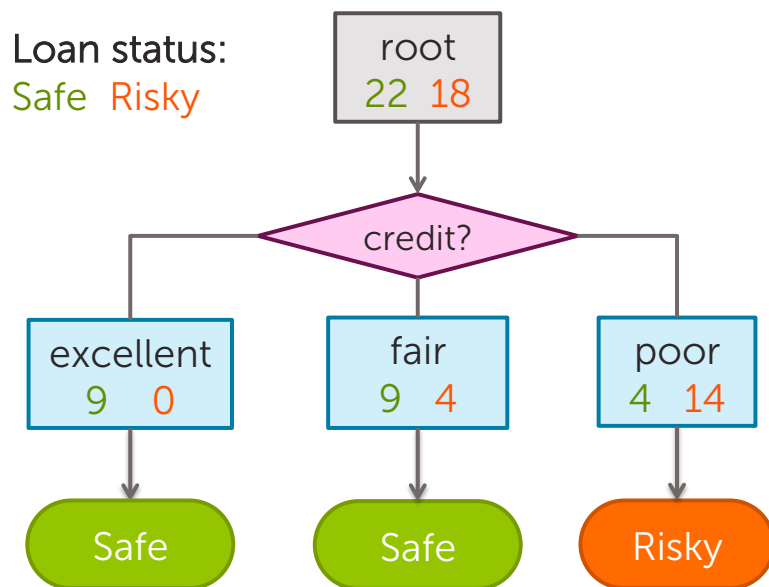

Decision stump: Single level tree

Visual Notation: Intermediate nodes

Making predictions with a decision stump

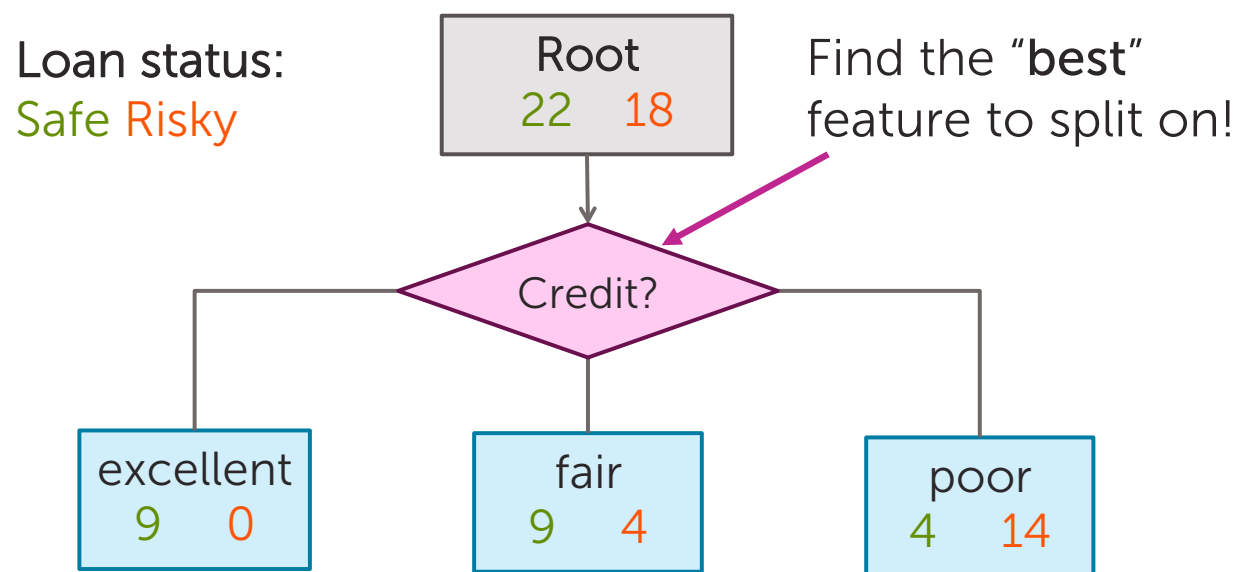

But before we split further, we're going to discuss why we picked credit to do the first split as opposed to say, for example, the term of the loan or income.

For each intermediate node,
set \hat{y} = majority value

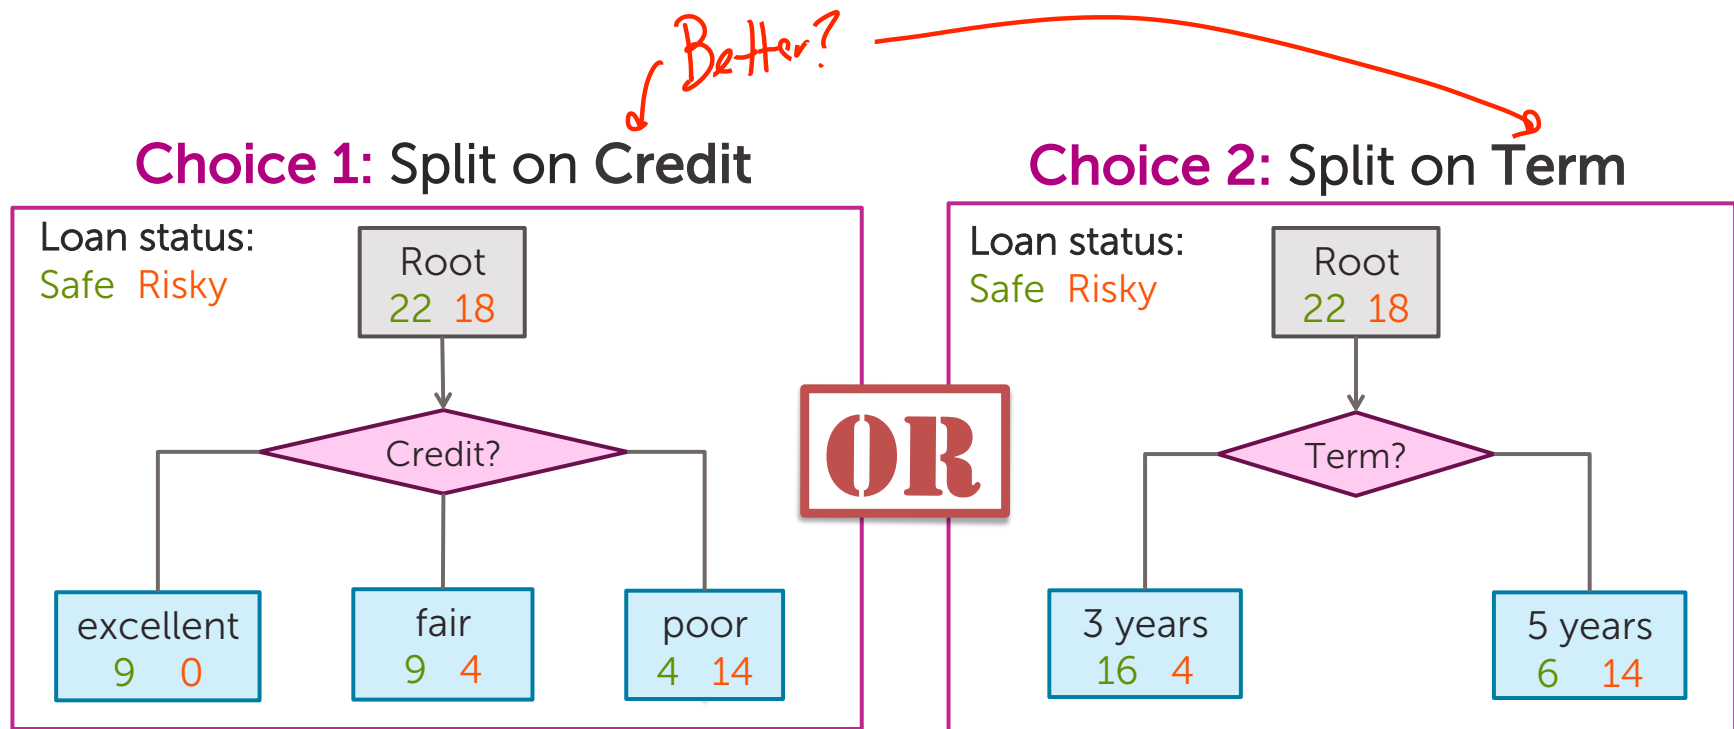

Selecting best feature to split on

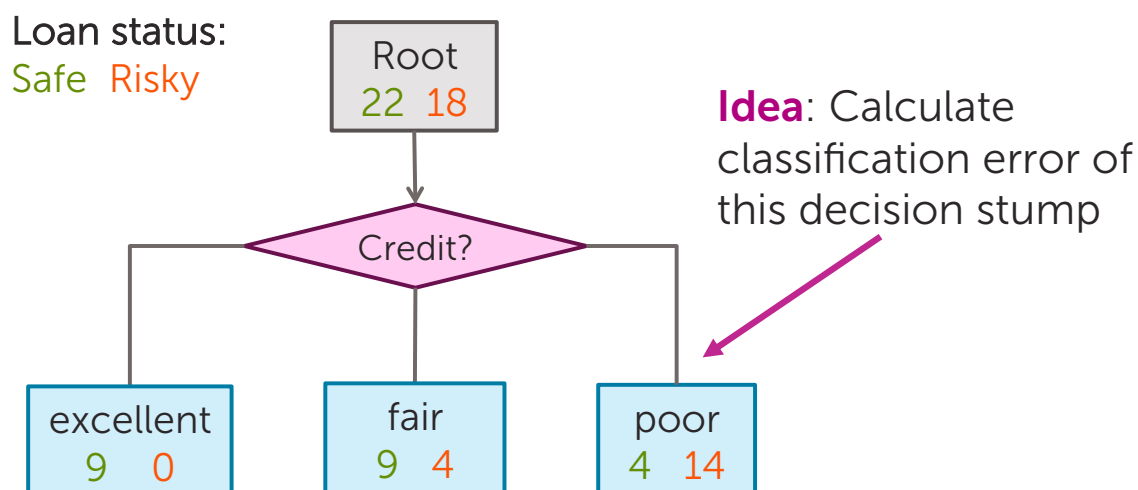

How do we learn a decision stump?

How do we select the best feature?

How do we measure effectiveness of a split?

$$\text{Error} = \frac{\text{\# mistakes}}{\text{\# data points}}$$

Calculating classification error

- **Step 1:** \hat{y} = class of majority of data in node
- **Step 2:** Calculate classification error of predicting \hat{y} for this data

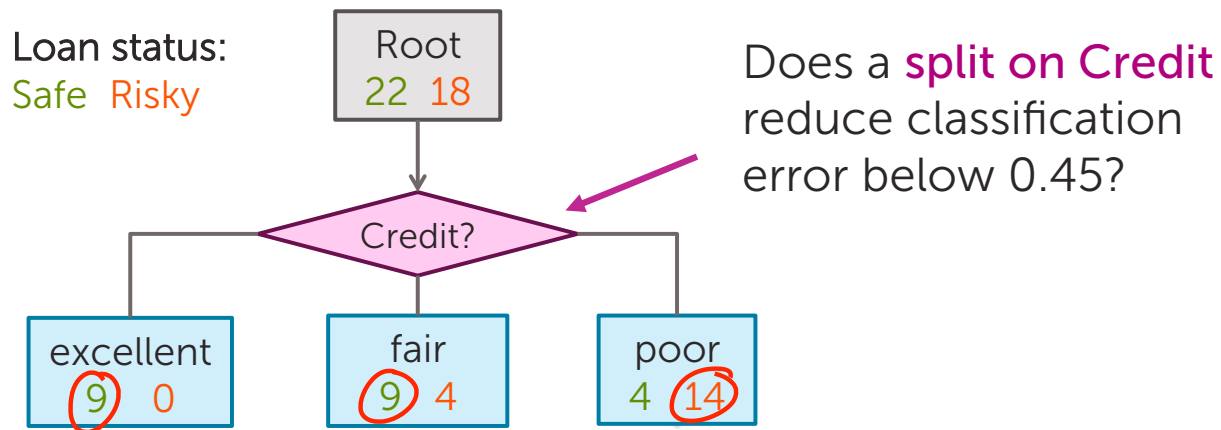

$$\text{Error} = \frac{18}{22+18}$$
$$= 0.45$$

Tree	Classification error
(root)	0.45

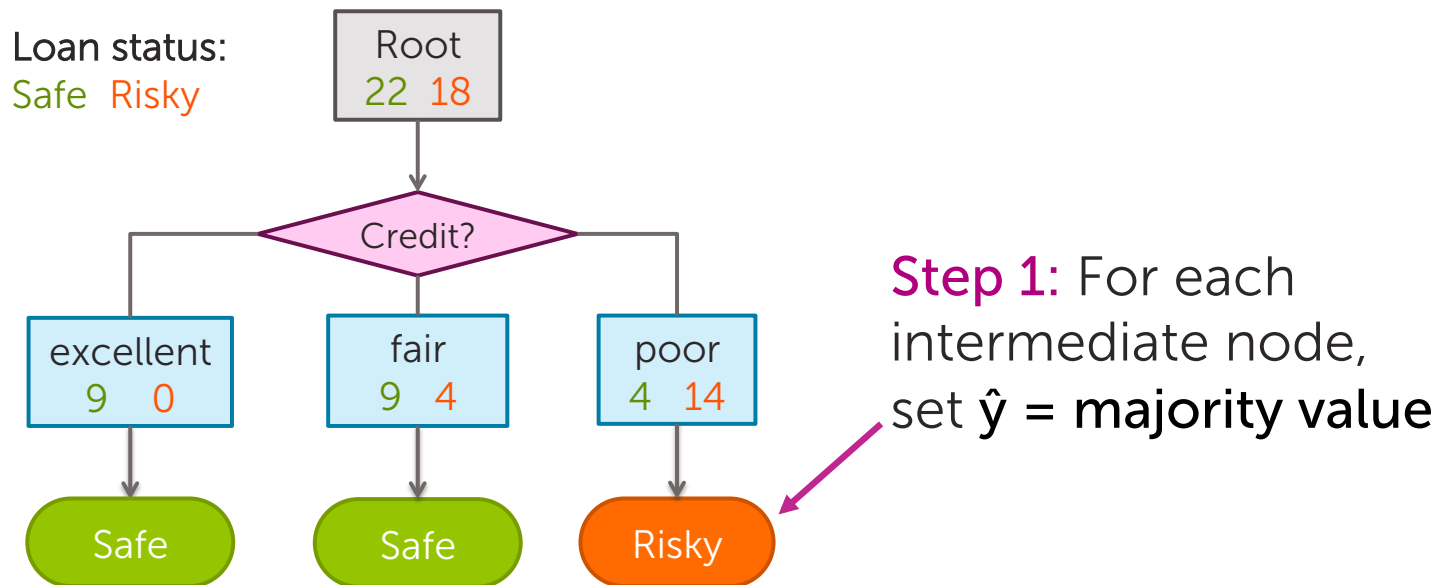

Choice 1: Split on credit history?

Choice 1: Split on Credit

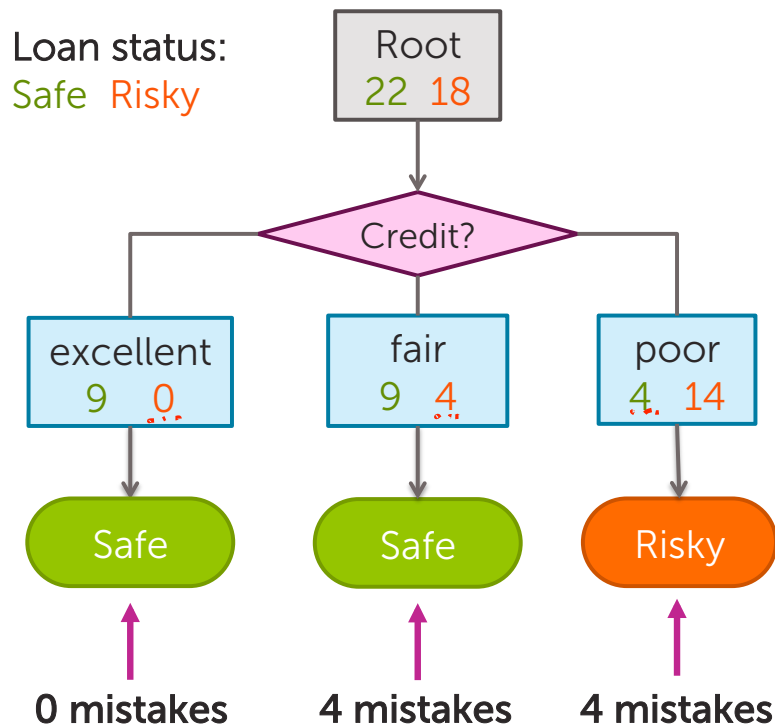

How good is the split on Credit?

Choice 1: Split on Credit

Split on Credit: Classification error

Choice 1: Split on Credit

$$\text{Error} = \frac{4 + 4}{40} = 0.20$$

Tree	Classification error
(root)	0.45
Split on credit	0.2

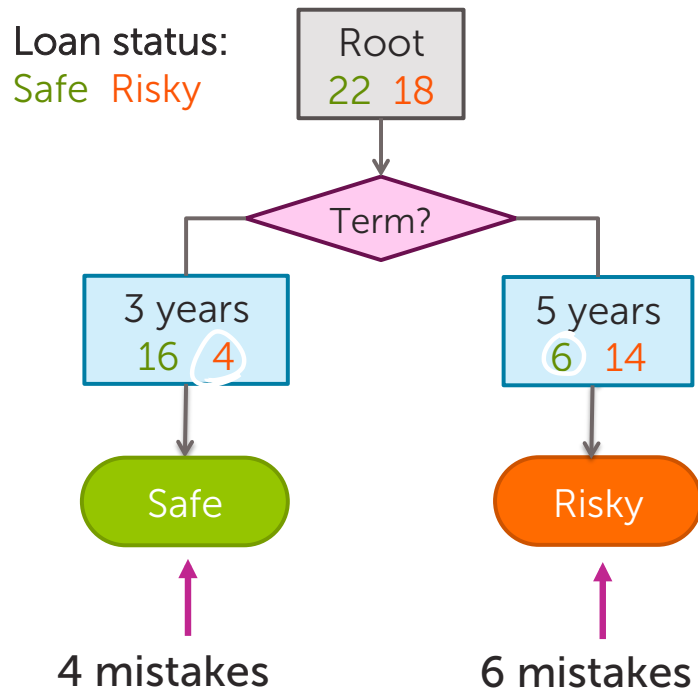

Choice 2: Split on Term?

Choice 2: Split on Term

Evaluating the split on Term

Choice 2: Split on Term

$$\text{Error} = \frac{4 + 6}{40} = 0.25$$

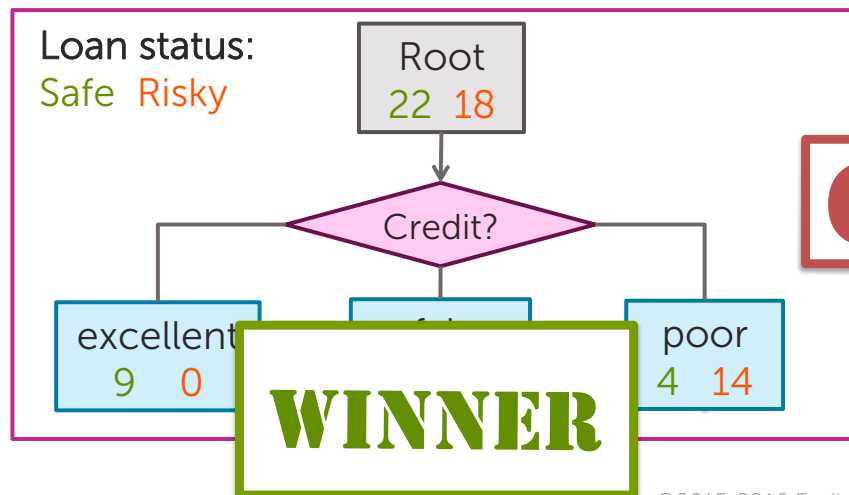

Tree	Classification error
(root)	0.45
Split on credit	0.2
Split on term	0.25

Choice 1 vs Choice 2

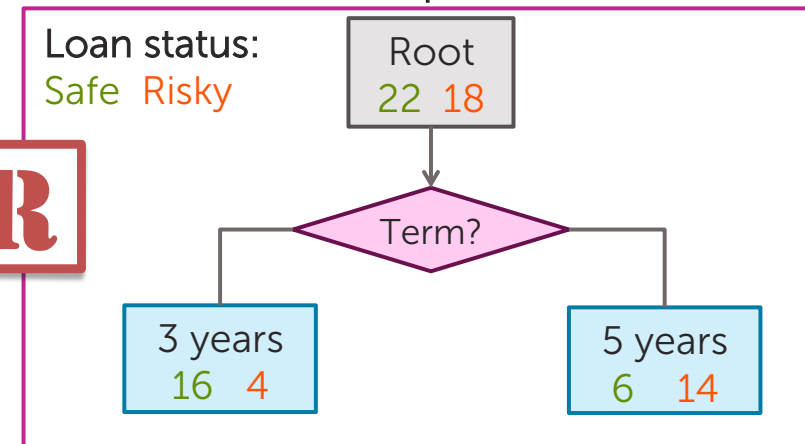

Tree	Classification error
(root)	0.45
split on <u>credit</u>	0.2
split on loan term	0.25

← First split!

Choice 1: Split on Credit

Choice 2: Split on Term

OR

Feature split selection algorithm

- Given a subset of data M (a node in a tree)
- For each feature $h_j(x)$: *credit, term, income*
 1. Split data of M according to feature $h_j(x)$
 2. Compute classification error split
- Chose feature $h^*(x)$ with lowest classification error *credit*

Greedy decision tree learning

- Step 1: Start with an empty tree
- Step 2: Select a feature to split data
- For each split of the tree:
 - Step 3: If nothing more to, make predictions
 - Step 4: Otherwise, go to Step 2 & continue (recurse) on this split

Pick feature split
leading to lowest
classification error

Decision Tree Learning:

Recursion & Stopping conditions

Learn decision tree from data?

Credit	Term	Income	y
excellent	3 yrs	high	safe
fair	5 yrs	low	risky
fair	3 yrs	high	safe
poor	5 yrs	high	risky
excellent	3 yrs	low	risky
fair	5 yrs	low	safe
poor	3 yrs	high	risky
poor	5 yrs	low	safe
fair	3 yrs	high	safe

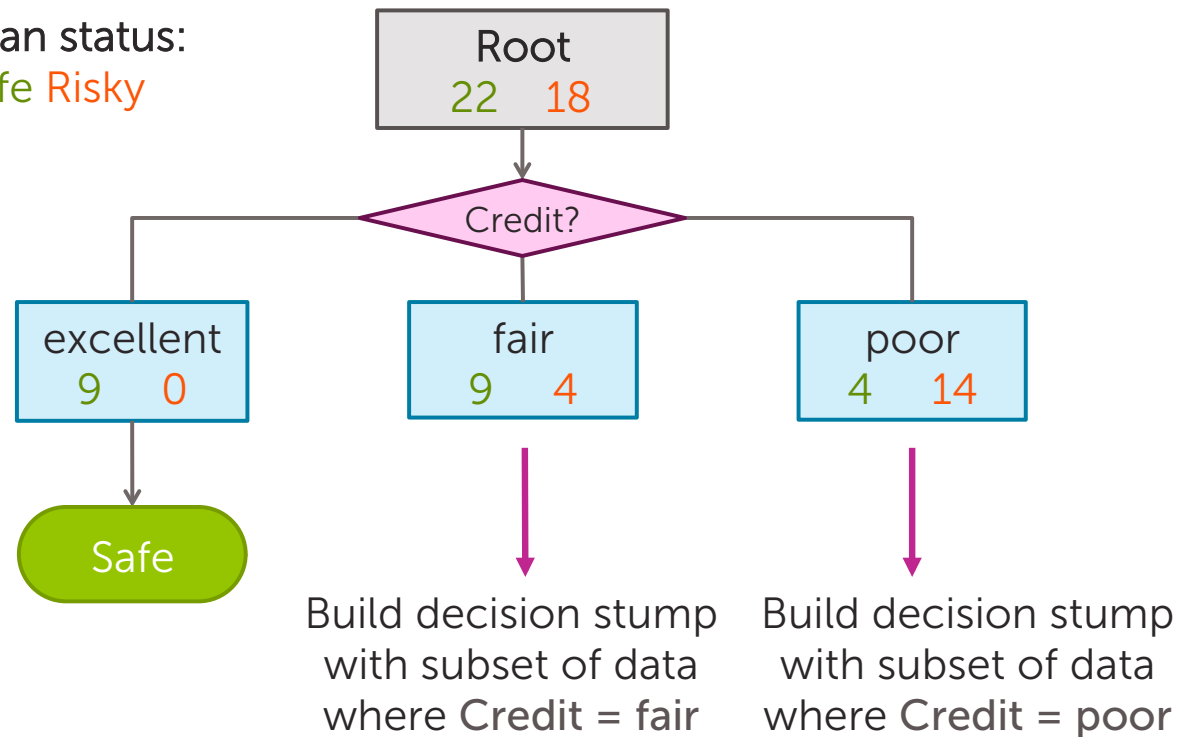

We've learned a decision stump, what next?

Loan status:
Safe Risky

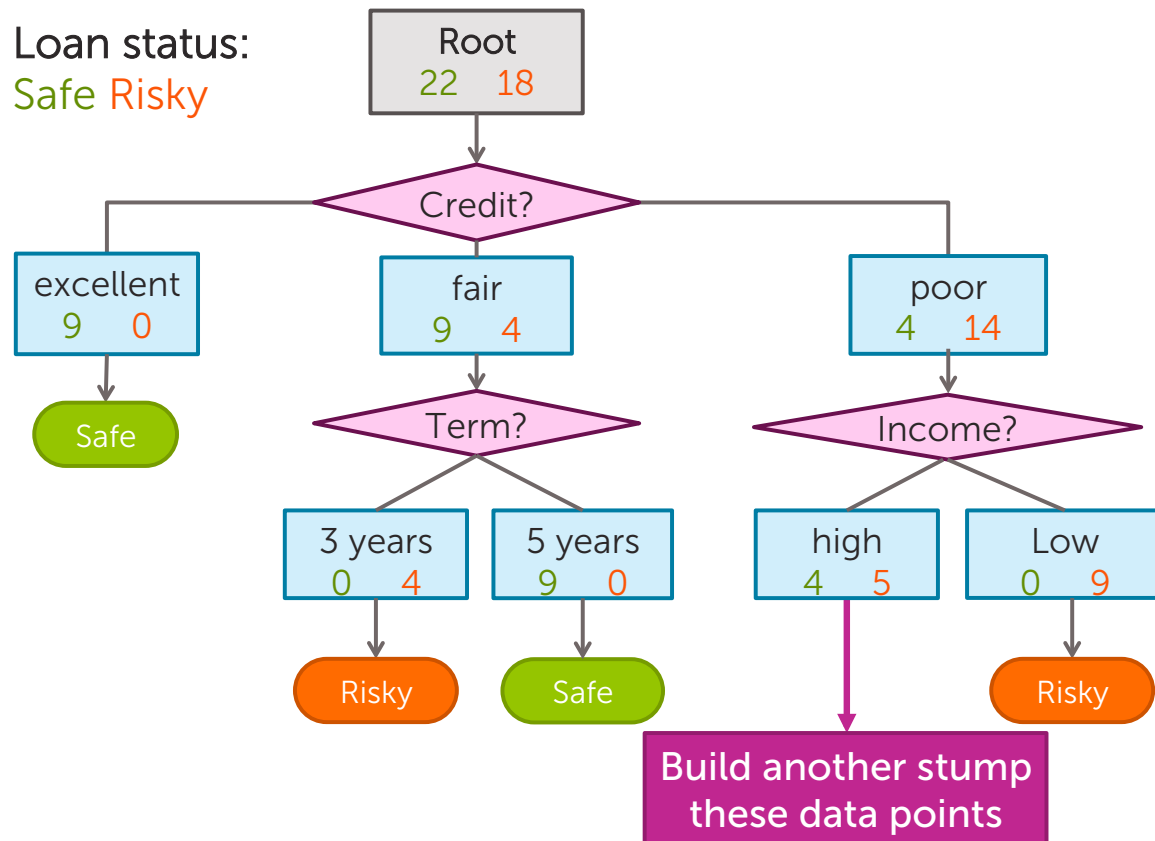

Tree learning = Recursive stump learning

Loan status:
Safe Risky

Second level

Final decision tree

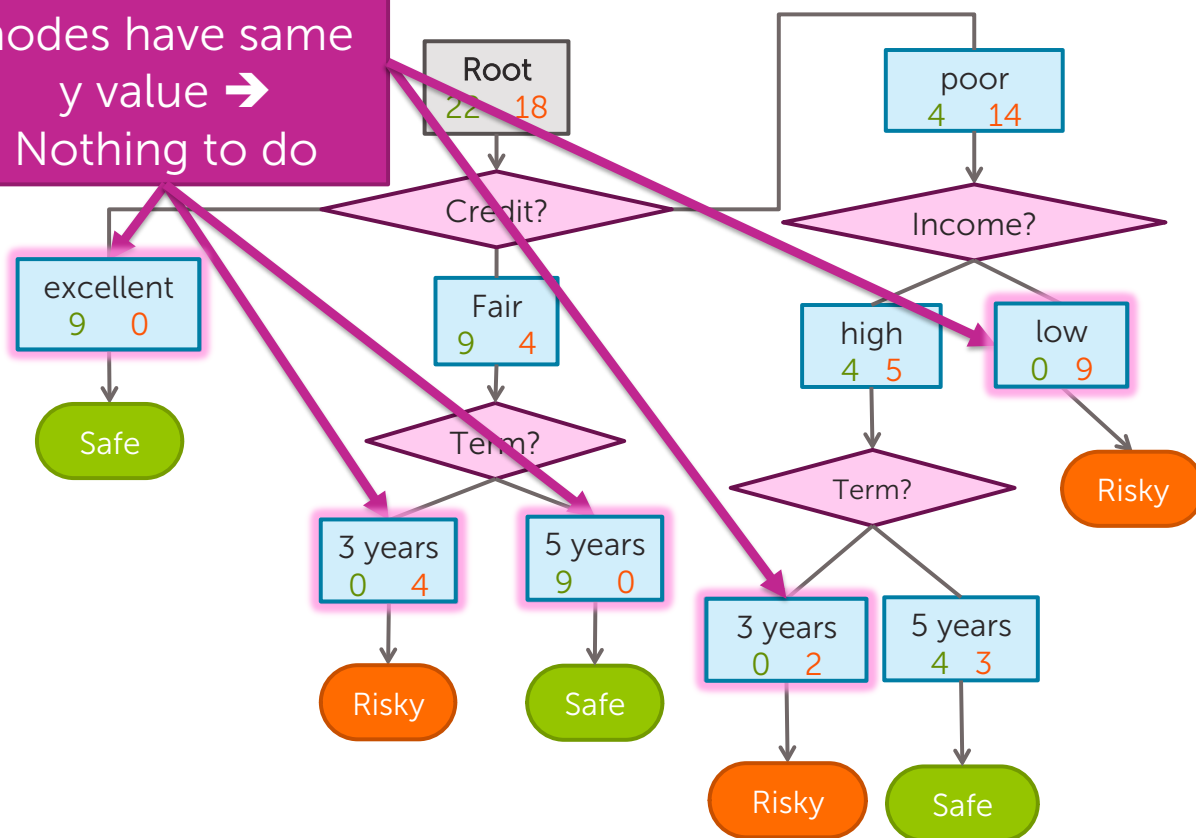

Simple greedy decision tree learning

Stopping condition 1: All data agrees on y

All data in these nodes have same y value → Nothing to do

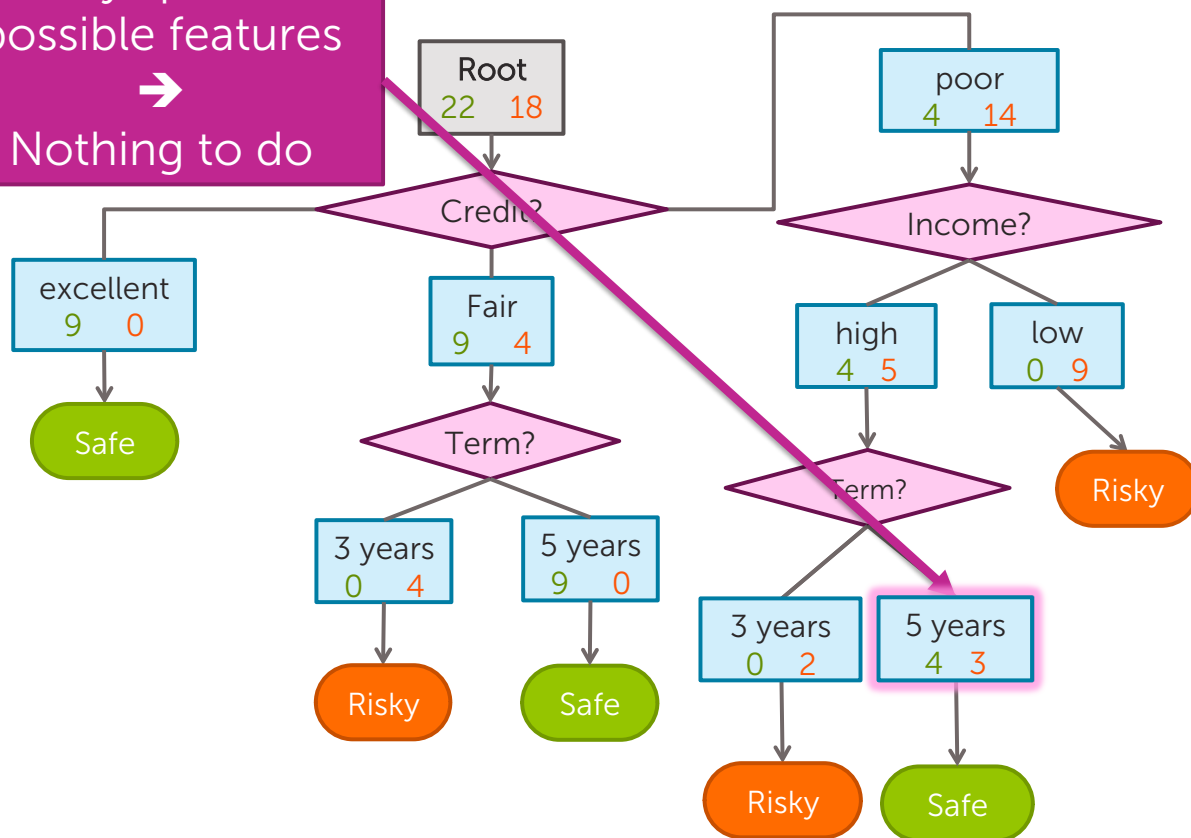

Stopping condition 2: Already split on all features

Already split on all
possible features

Nothing to do

Greedy decision tree learning

- **Step 1:** Start with an empty tree

- **Step 2:** Select a feature to split data

- For each split of the tree:

- **Step 3:** If nothing more to, make predictions

- **Step 4:** Otherwise, go to **Step 2** & continue (recurse) on this split

Pick feature split leading to lowest classification error

Stopping conditions 1 & 2

Recursion

Predictions with decision trees

Decision tree model

Traversing a decision tree

$\mathbf{x}_i = (\text{Credit} = \text{poor}, \text{Income} = \text{high}, \text{Term} = 5 \text{ years})$

Decision tree prediction algorithm

predict(tree_node, input)

- If current tree_node is a leaf:
 - **return** majority class of data points in leaf
- else:
 - next_note = child node of tree_node whose feature value agrees with input
 - **return predict**(next_note, input)

Multiclass classification & predicting probabilities

Multiclass prediction

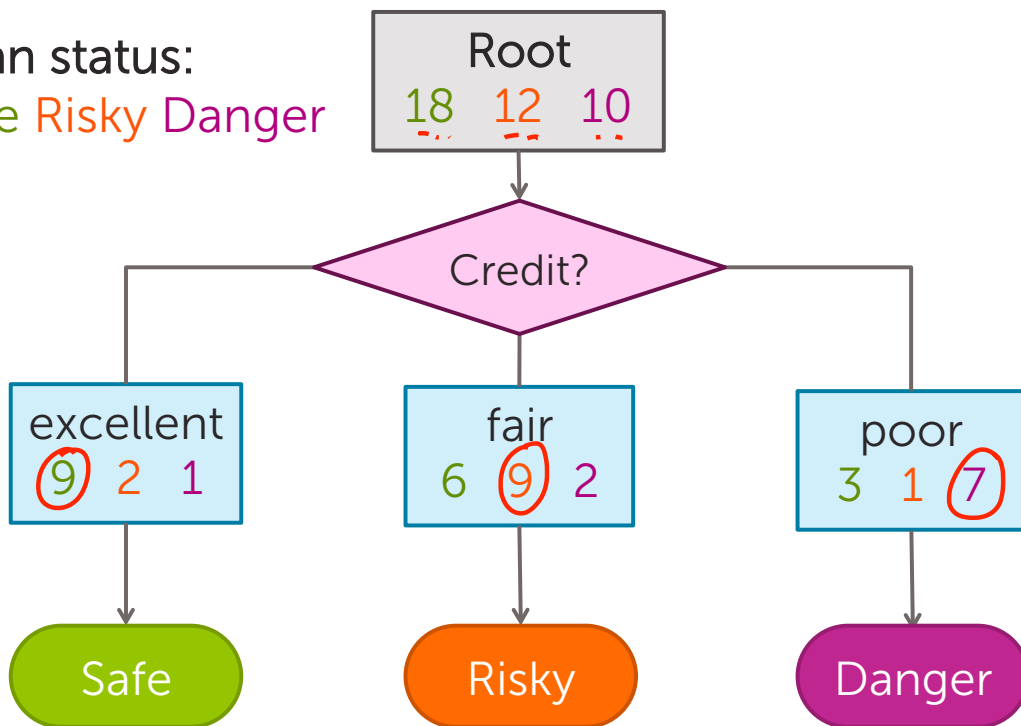

Multiclass decision stump

$N = 40$,
1 feature,
3 classes

Credit	y
excellent	<u>safe</u>
fair	<u>risky</u>
fair	safe
poor	<u>danger</u>
excellent	risky
fair	safe
poor	danger
poor	safe
fair	safe
...	...

Loan status:
Safe Risky Danger

Predicting probabilities with decision trees

Decision tree learning:

Real valued features

How do we use real values inputs?

Income	Credit	Term	y
\$105 K	excellent	3 yrs	Safe
\$112 K	good	5 yrs	Risky
\$73 K	fair	3 yrs	Safe
\$69 K	excellent	5 yrs	Safe
\$217 K	excellent	3 yrs	Risky
\$120 K	good	5 yrs	Safe
\$64 K	fair	3 yrs	Risky
\$340 K	excellent	5 yrs	Safe
\$60 K	good	3 yrs	Risky

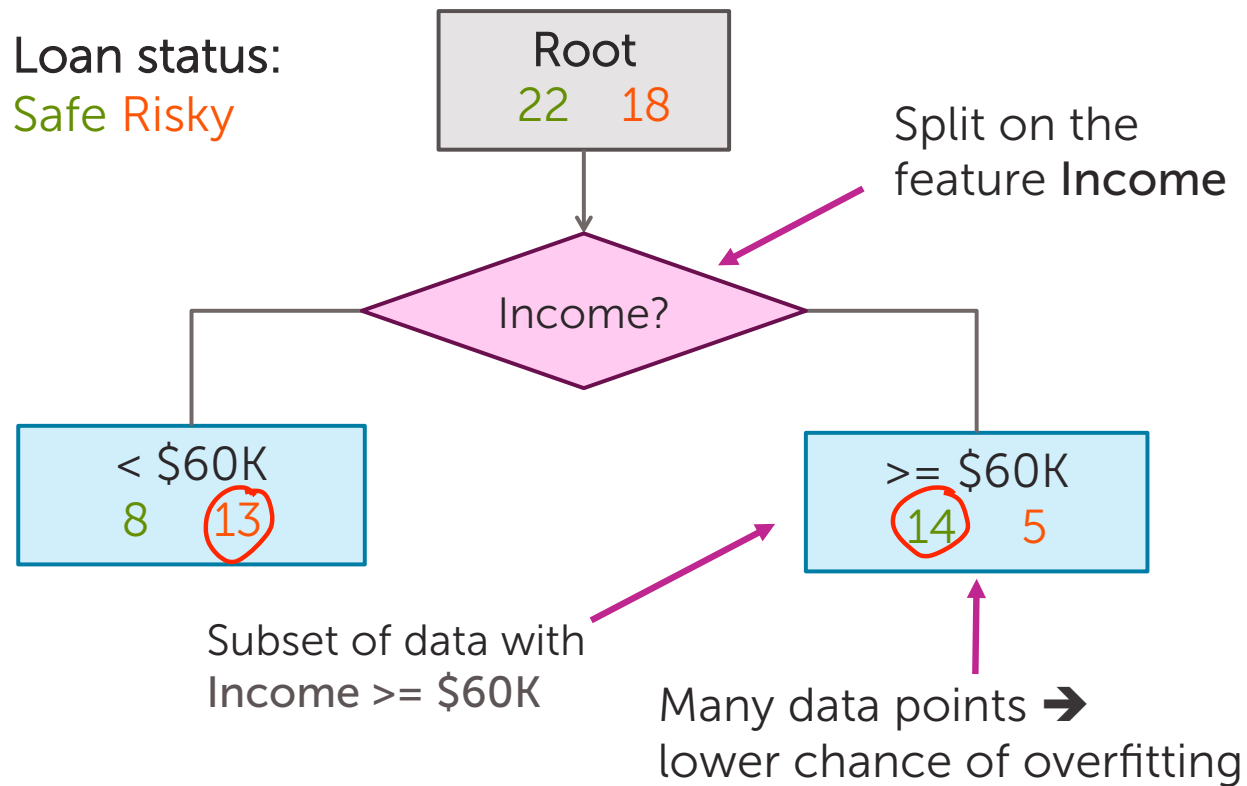

Split on each numeric value?

Danger: May only contain one data point per node

Loan status:
Safe Risky

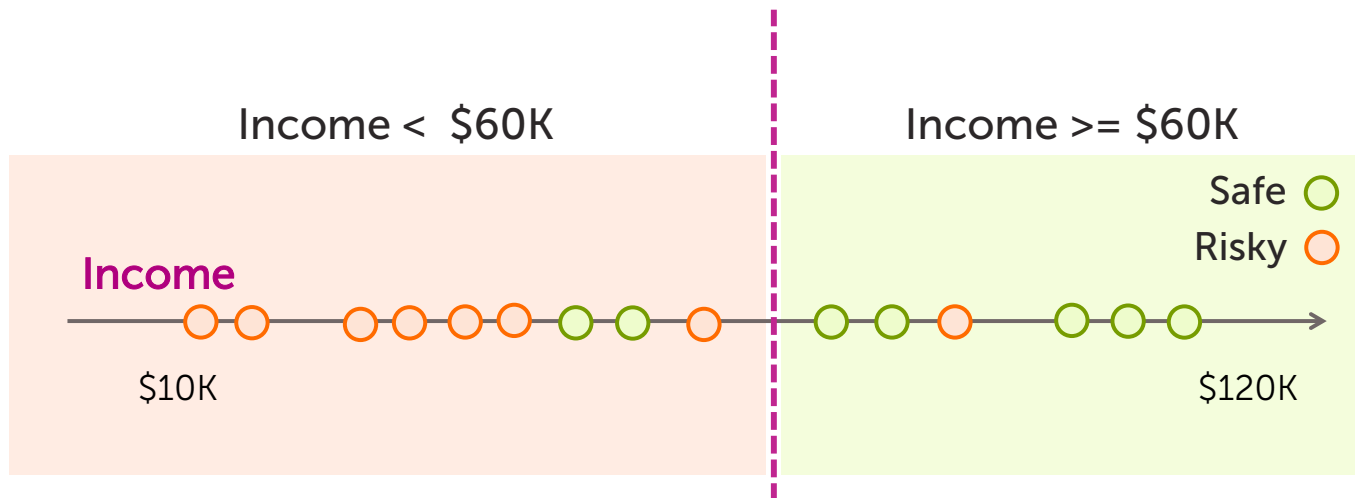

Alternative: Threshold split

Threshold splits in 1-D

Threshold split is the line
 $\text{Income} = \$60\text{K}$

Visualizing the threshold split

Split on Age ≥ 38

Depth 2: Split on Income \geq \$60K

Finding the best threshold split

OPTIONAL

Finding the best threshold split

Infinite possible
values of t

Income = t^*

Consider a threshold between points

Same **classification error** for any threshold split between v_A and v_B

Only need to consider mid-points

Finite number of
splits to consider

Threshold split selection algorithm

- **Step 1:** Sort the values of a feature $h_j(\mathbf{x})$:
Let $\{v_1, v_2, v_3, \dots, v_N\}$ denote sorted values
- **Step 2:**
 - For $i = 1 \dots N-1$
 - Consider split $t_i = (v_i + v_{i+1}) / 2$
 - Compute classification error for threshold split $h_j(\mathbf{x}) \geq t_i$
 - Chose the t^* with the lowest classification error

✓ income

Decision trees vs logistic regression:

Example

Logistic regression

Feature	Value	Weight Learned
$h_0(\mathbf{x})$	1	0.22
$h_1(\mathbf{x})$	$x[1]$	1.12
$h_2(\mathbf{x})$	$x[2]$	-1.07

data

Depth 1: Split on $x[1]$

y values
- +

Depth 2

y values
- +

Threshold split caveat

Decision boundaries

Comparing decision boundaries

Decision Tree

Logistic Regression

Summary of decision trees

What you can do now

- Define a decision tree classifier
- Interpret the output of a decision trees
- Learn a decision tree classifier using greedy algorithm
- Traverse a decision tree to make predictions
 - Majority class predictions
 - Probability predictions
 - Multiclass classification
